(54) Drive and brake assembly

(57) An aircraft belt loader having a level frame which has an elevation from the ground which is lower than the centre of rotation (70) for the wheels (24,26) supporting the loader; the drive arrangement comprising an electric motor (42) having an output shaft (52), a mounting ring (38) releasably secured to the motor, a vertical support plate (28) affixed to the frame members (30,32) and having a circular opening (34) with a centre elevated above the frame members, a flange (36) secured in the opening, cap screws or bolts (40) releasably securing the ring to the flange, a planetary reducer (50) having an input connection to receive the output shaft (52) a rotatable output casing (56), and a mounting plate (46) rotatably supporting the drive; bolts (48) releasably securing the mounting plate (46) to the flange (36), and a ground-engaging drive wheel (26) affixed to the casing; the brake assembly comprising a brake ring (86) secured to the casing (56), a sleeve (84) affixed to the brake ring, a rotor (82) affixed to the sleeve and a hydraulically-activated caliper (74) carried by the support plate (28) for engagement with the rotor.

FIG. 3

SPECIFICATION

Drive and brake assembly

This invention relates generally to drive and
 5 brake assemblies, and more particularly to such assemblies for use in aircraft belt loaders.

The overall height of aircraft belt loaders is important since such loaders must operate
 10 around and in close proximity to the aircraft they service. It is, therefore, desirable to provide a level frame which has an elevation from the ground which is lower than the center of rotation for the wheels supporting
 15 the loader. The present invention provides such an arrangement. It is also compact and relatively easy to assemble and service. These and other attributes and desirable features of the present invention will become more readily apparent from a perusal of the following description and the accompanying drawings, wherein:

Figure 1 is a side elevational view of an aircraft belt loader incorporating the present
 25 invention;

Figure 2 is a cross-sectional view taken on line 2-2 of Fig. 1; and

Figure 3 is a side elevational view of the invention as incorporated in Fig. 1, looking
 30 from the inside toward the outside of the loader.

Referring to Fig. 1, an aircraft belt loader is indicated generally by 10, and includes a belt conveyor 12 mounted on links 14 and 16
 35 which are pivoted to the frame 18 of the loader and angularly controlled by independent hydraulic cylinders, one of which is shown at 20.

The power for traction and for an electric
 40 motor to drive the hydraulic pump in the hydraulic circuit is provided by a battery pack which is concealed under cover 22. The battery pack substantially fills the space between the front steerable wheel 24 and the rear
 45 drive wheel 26 on one side of the machine. The battery pack requires a level frame, at least in the length of its frame support, and to keep the wheel base as short as possible, the frame must be level. The overall height of the
 50 loader must be as low as possible, which requires that the frame be below the axis of rotation of the drive wheel 26, at least for tire diameters commercially available and capable of carrying the loads imposed thereon by the
 55 loader.

A vertical plate 28 is attached to the ends of box members 30 and 32 which form a part of the frame 12, as best seen in Fig. 3. A circular opening 34 is provided in the plate
 60 28 and a circular flange member 36 fits into the opening and is secured, such as by welding, to the plate 28. A ring 38 is attached to the flange 36 by means of cap screws or bolts 40 and to an electric motor 42 by bolts 44.
 65 The flange 36 is piloted on a mounting plate

46 and secured thereto by bolts 48. The mounting plate 46 is part of a planetary reducer 50 sold by the Fairfield Manufacturing Company of Lafayette, Indiana and referred to as "Torque-Hubs". The output shaft 52 of electric motor 42 is splined at 54 to mate with a compatible, internally splined connector in the planetary drive. The output of the drive 50 is through its rotating casing
 70 or housing 56. A drive wheel 58 includes a rim 60 to which an interior flange 62 is welded. The flange 62 is attached to a flange 64 on casing 56 by bolts 66.

The center of rotation for the wheel 58 is aligned with the center of rotation for the
 80 motor 42 as represented by the dot 70 on Fig. 3. It can be seen that the center 70 is above the box members 30 and 32. The frame 12 can, therefore, be level, i.e. not utilize any bends in a vertical plane, to provide a platform for the battery pack. The wheelbase can be maintained as short as possible and the proper sized tire to accommodate the loading utilized.

90 The support plate 28 has a cut-out or opening 72 to accept a hydraulically activated disk brake 74. The brake 74 is retained within the cut-out 72 by a plate 76 held on the plate 28 by bolts 78 and secured to the brake 74
 95 by bolts 80. A rotor 82 mounted to rotate between the caliper of brake 74 by being secured to a sleeve 84 affixed to a ring 86 which is bolted to the casing 56 by bolts 88. A mechanically-actuated parking brake 90 may also be provided. This brake is also secured within a cut-out or opening 92 in the support plate 28 and held by a plate 94; bolts 96 attaching the plate 94 to the plate 28 and bolts 98 attaching the plate 94 to the brake
 100 90. The brake 90 includes a rotatable lever 100 which is pivotally attached to the actuator wire 102 which is reciprocable with a sheath 104 of a Bowden cable. The sheath is mounted on the plate 28 by a bracket 106.

105 The compactness of this arrangement is apparent from Fig. 2, which shows that the rotor 82 extends only a short distance from the tire in the inboard/outboard direction and occupies no more space in this direction than the
 110 mounting of the planetary drive. Also, the fact that both of the brakes 74 and 70 are mounted to take advantage of the support plates' thickness to reduce the space, in an inboard/outboard direction. The major extension of these brakes is toward the wheel 58 which is a distance already spanned by the mounting of the planetary drive 50. The arrangement of the present invention permits a compact drive and brake arrangement, which
 115 is especially useful in aircraft belt loaders wherein clearance, for the links and associated cylinders, dictates that the motor/wheel distance be kept to a minimum.

1. A drive arrangement for a vehicle having a frame comprising:
 - an electric motor having an output shaft;
 - a mounting ring releasably secured to said motor;
 - a vertical support plate affixed to said frame and having a circular opening with a center elevated above said frame;
 - a flange secured in said opening;
- 10 first means releasably securing said ring to said flange;
- 15 a planetary reducer having an input connection to receive said output shaft, rotatable output casing, and a mounting plate rotatably supporting said drive;
 - second means releasably securing said mounting plate to said flange; and
 - a ground-engaging drive wheel affixed to said casing.
- 20 2. The invention according to claim 1 and further comprising:
 - a brake ring secured to said casing;
 - a sleeve affixed to said brake ring;
 - a rotor affixed to said sleeve; and
- 25 25 a hydraulically-activated caliper carried by said support plate for engagement with said rotor.
- 30 3. The invention according to claim 2, and further comprising:
 - 30 a mechanically actuated brake engageable with said rotor and having a lever arm; and
 - a bowden cable having a sheath supported from said support plate and an actuating wire attached to said lever arm.
- 35 4. In an aircraft belt loader having a frame, a drive arrangement to achieve a level frame which is below the center of wheel rotation, comprising:
 - an electric motor having an output shaft;
- 40 40 a mounting ring releasably secured to said motor;
 - a vertical support plate affixed to said frame and having a circular opening therein;
 - said circular opening having a center ele-
- 45 45 vated above said frame;
 - a flange positioned in said opening and secured to said support plate;
 - first means releasably securing said ring to said flange;
- 50 50 a planetary reducer having an input connection for receipt of said output shaft;
 - said reducer having a rotatable output housing and a mounting plate rotatably supporting said drive;
- 55 55 second means releasably securing said mounting plate to said flange; and
- 55 a ground-engaging drive wheel affixed to said casing.
- 60 5. The invention according to claim 4, and further comprising:
 - a brake ring secured to said casing;
 - a sleeve affixed to said brake ring;
 - a rotor affixed to said sleeve; and
- 65 65 a hydraulically-activated caliper carried by said support plate for engagement with said

rotor.

6. The invention according to claim 5, and further comprising:
 - a mechanically actuated brake carried by said support plate and engageable with said rotor.
7. A drive arrangement for a vehicle as claimed in Claim 1 or an aircraft belt loader incorporating a drive arrangement as claimed in Claim 4 and substantially as described with reference to or as shown by the Drawings.
